SE Labs tested a variety of anti-malware (aka ‘anti-virus’; aka ‘endpoint security’) products from a range of well-known vendors in an effort to judge which were the most effective.

Each product was exposed to the same threats, which were a mixture of targeted attacks using well-established techniques and public email and web-based threats that were found to be live on the internet at the time of the test.

The results indicate how effectively the products were at detecting and/or protecting against those threats in real time.

Document version 1.0 Written 5th August 2020
INTRODUCTION

Next-gen testing for next-gen security products
Bad guys help SE Labs keep its testing up to date

For the first time in our endpoint protection tests we’ve seen a strong overall performance from both well-established anti-malware brands and newer entrants to the market.

While vendors such as FireEye and Crowdstrike are today well-known and respected brands in the security world, they are relatively new compared to the likes of Symantec, McAfee and even Microsoft, which has not promoted heavily its anti-malware software until quite recently.

It is reassuring to see that behind some of the aggressive marketing campaigns from the last few years there has been truly effective innovation.

Since late 2019 SE Labs has tested publicly so-called ‘next-generation’ products from companies such as SentinelOne, FireEye, Crowdstrike and Sophos. Other, older vendors may not have released products that appeared to be ‘new’ but, in fact, most continually develop their products even if they don’t rename them. Microsoft Defender, for example, has come on in leaps and bounds, in terms of protection performance, over the last two years. Arguably today’s version of Defender is as much a ‘next-gen’ product as anything new coming out of Silicon Valley.

The reason that we’re trusted by these vendors to test their products is because our testing is also ‘next-gen’, meaning that we’re continually innovating and ensuring that the tests we run are accurate, relevant and transparent.

We do this by closely monitoring the highest quality threat intelligence, so that we only use the most important threats available that are affecting victims over the same time period as we test. In some cases the bad guys actually help us out, by sending our own organisation the same types of malware that they use to target other potential victims. The Emotet malware campaign that ran in July of this year was a notable example.

To maintain transparency we explain in detail how we run each test without each report, publish detailed methodologies on our website and run all of our public tests according to the AMTSO Testing Protocol Standard for maximum transparency.

The top-grade results and analysis in this report come to you courtesy of the hard work and diligence of our in-house hacker testers and the ‘cooperation’ of criminals on the internet attacking us!

If you spot a detail in this report that you don’t understand, or would like to discuss, please contact us via our Twitter or Facebook accounts. SE Labs uses current threat intelligence to make our tests as realistic as possible. To learn more about how we test, how we define ‘threat intelligence’ and how we use it to improve our tests please visit our website and follow us on Twitter.

This test report was funded by post-test consultation services provided by SE Labs to security vendors. Vendors of all products included in this report were able to request early access to results and the ability to dispute details for free. SE Labs has submitted the testing process behind this report for compliance with the AMTSO Testing Protocol Standard v1.3. To verify its compliance please check the AMTSO reference link at the bottom of page three of this report or here.
Executive Summary

Product Names
It is good practice to stay up to date with the latest version of your chosen endpoint security product. We made best efforts to ensure that each product tested was the very latest version running with the most recent updates to give the best possible outcome.

For specific build numbers, see Appendix C: Product Versions on page 19.

- The endpoints were generally effective at handling general threats from cyber criminals...
  Most products were largely capable of handling public web-based threats such as those used by criminals to attack Windows PCs, tricking users into running malicious files or running scripts that download and run malicious files. All but three were 100 per cent effective.

- .. and targeted attacks were prevented in most cases.
  All but one of the products were completely effective at blocking more targeted, exploit-based attacks. The exception was Bitdefender.

- False positives were not an issue for the products
  All of the endpoint solutions were good at correctly classifying legitimate applications and websites. They allowed all of the legitimate websites and applications with the exception of the products from Microsoft, Sophos and Webroot, which blocked one or two each.

- Which products were the most effective?
  Products from Kaspersky Lab, McAfee, Microsoft, Sophos, Symantec, Trend Micro achieved extremely good results due to a combination of their ability to block malicious URLs, handle exploits and correctly classify legitimate applications and websites. Along with products from Bitdefender and FireEye, they achieved AAA awards.

Products highlighted in green were the most accurate, scoring 85 per cent or more for Total Accuracy. Those in yellow scored less than 85 but 75 or more. Products shown in red scored less than 75 per cent.

For exact percentages, see 1. Total Accuracy Ratings on page 6.
1. Total Accuracy Ratings

Judging the effectiveness of an endpoint security product is a subtle art, and many factors are at play when assessing how well it performs. To make things easier we’ve combined all the different results from this report into one easy-to-understand graph.

The graph below takes into account not only each product’s ability to detect and protect against threats, but also its handling of non-malicious objects such as web addresses (URLs) and applications.

Not all protections, or detections for that matter, are equal. A product might completely block a URL, which stops the threat before it can even start its intended series of malicious events. Alternatively, the product might allow a web-based exploit to execute but prevent it from downloading any further code to the target. In another case malware might run on the target for a short while before its behaviour is detected and its code is deleted or moved to a safe ‘quarantine’ area for future analysis. We take these outcomes into account when attributing points that form final ratings.

For example, a product that completely blocks a threat is rated more highly than one that allows a threat to run for a while before eventually evicting it. Products that allow all malware infections, or that block popular legitimate applications, are penalised heavily.

Categorising how a product handles legitimate objects is complex, and you can find out how we do it in 6. Legitimate Software Ratings on page 14.

Small Business Endpoint Protection Awards

The following products win SE Labs awards:

- Kaspersky Small Office Security
- McAfee Endpoint Security
- Sophos Intercept X
- Microsoft Defender Antivirus – Enterprise
- Symantec Endpoint Security Enterprise Edition
- Trend Micro Worry Free Security Services
- Bitdefender Gravity Zone Endpoint Security
- FireEye Endpoint Security

- Webroot SecureAnywhere Endpoint Protection
2. Threat Responses

Full Attack Chain: Testing every layer of detection and protection

Attackers start from a certain point and don’t stop until they have either achieved their goal or have reached the end of their resources (which could be a deadline or the limit of their abilities). This means, in a test, the tester needs to begin the attack from a realistic first position, such as sending a phishing email or setting up an infected website, and moving through many of the likely steps leading to actually stealing data or causing some other form of damage to the network.

If the test starts too far into the attack chain, such as executing malware on an endpoint, then many products will be denied opportunities to use the full extent of their protection and detection abilities. If the test concludes before any ‘useful’ damage or theft has been achieved, then similarly the product may be denied a chance to demonstrate its abilities in behavioural detection and so on.

**Attack stages**

The illustration below shows some typical stages of an attack. In a test each of these should be attempted to determine the security solution’s effectiveness. This test’s results record detection and protection for each of these stages.

We measure how a product responds to the first stages of the attack with a detection and/or protection rating. Sometimes products allow threats to run but detect them. Other times they might allow the threat to run briefly before neutralising it. Ideally they detect and block the threat before it has a chance to run. Products may delete threats or automatically contain them in a ‘quarantine’ or other safe holding mechanism for later analysis.

Should the initial attack phase succeed we then measure post-exploitation stages, which are represented by steps two through to seven below. We broadly categorise these stages as: Access (step 2); Action (step 3); Escalation (step 4); and Post-escalation (step 5).

**In figure 1.** you can see a typical attack running from start to end, through various ‘hacking’ activities. This can be classified as a fully successful breach.

**In figure 2.** a product or service has interfered with the attack, allowing it to succeed only as far as stage 3, after which it was detected and neutralised. The attacker was unable to progress through stages 4 and onwards.
It is possible that attackers will not cause noticeable damage during an attack. It may be that their goal is persistent presence on the systems to monitor for activities, slowly steal information and other more subtle missions.

In figure 3, the attacker has managed to progress as far as stage five. This means that the system has been seriously compromised. The attacker has a high level of access and has stolen passwords. However, attempts to exfiltrate data from the target were blocked, as were attempts to damage the system.

**ATTACK CHAIN:** How Hackers Progress

**Figure 1.** A typical attack starts with an initial contact and progresses through various stages, including reconnaissance, stealing data and causing damage.

**Figure 2.** This attack was initially successful but only able to progress as far as the reconnaissance phase.

**Figure 3.** A more successful attack manages to steal passwords but wholesale data theft and destruction was blocked.
3. Protection Ratings

The results below indicate how effectively the products dealt with threats. Points are earned for detecting the threat and for either blocking or neutralising it.

- **Detected (+1)**
  If the product detects the threat with any degree of useful information, we award it one point.

- **Blocked (+2)**
  Threats that are disallowed from even starting their malicious activities are blocked. Blocking products score two points.

- **Complete Remediation (+1)**
  If, in addition to neutralising a threat, the product removes all significant traces of the attack, it gains an additional one point.

- **Neutralised (+1)**
  Products that kill all running malicious processes ‘neutralise’ the threat and win one point.

- **Persistent Neutralisation (-2)**
  This result occurs when a product continually blocks a persistent threat from achieving its aim, while not removing it from the system.

- **Compromised (-5)**
  If the threat compromises the system, the product loses five points. This loss may be reduced to four points if it manages to detect the threat (see Detected, above), as this at least alerts the user, who may now take steps to secure the system.

**Rating Calculations**
We calculate the protection ratings using the following formula:

\[
\text{Protection Rating} = (1 \times \text{number of Detected}) + (2 \times \text{number of Blocked}) + (1 \times \text{number of Neutralised}) + (1 \times \text{number of Complete remediation}) + (-5 \times \text{number of Compromised})
\]

The ‘Complete remediation’ number relates to cases of neutralisation in which all significant traces of the attack were removed from the target. Such traces should not exist if the threat was ‘Blocked’ and so Blocked results imply Complete remediation.

These ratings are based on our opinion of how important these different outcomes are. You may have a different view on how seriously you treat a ‘Compromise’ or ‘Neutralisation without complete remediation’. If you want to create your own rating system, you can use the raw data from 5. Protection Details on page 13 to roll your own set of personalised ratings.

**Targeted Attack Scoring**
The following scores apply only to targeted attacks and are cumulative, ranging from -1 to -5.

- **Access (-1)**
  If any command that yields information about the target system is successful this score is applied. Examples of successful commands include listing current running processes, exploring the file system and so on. If the first command is attempted and the session is terminated by the product without the command being successful the score of Neutralised (see above) will be applied.

- **Action (-1)**
  If the attacker is able to exfiltrate a document from the target’s Desktop of the currently logged in user then an ‘action’ has been successfully taken.

- **Escalation (-2)**
  The attacker attempts to escalate privileges to NT Authority/System. If successful, an additional two points are deducted.

- **Post-Escalation Action (-1)**
  After escalation the attacker attempts actions that rely on escalated privileges. These include attempting to steal credentials, modifying the file system and recording keystrokes. If any of these actions are successful then a further penalty of one point deduction is applied.
Protection Ratings are weighted to show that how products handle threats can be subtler than just ‘win’ or ‘lose’.

</tr>
</tbody>
</table>

Protection Scores are a simple count of how many times a product protected the system.
5. Protection Details

These results break down how each product handled threats into some detail. You can see how many detected a threat and the levels of protection provided.

Products sometimes detect more threats than they protect against. This can happen when they recognise an element of the threat but aren’t equipped to stop it. Products can also provide protection even if they don’t detect certain threats. Some threats abort on detecting specific endpoint protection software.

6. Legitimate Software Ratings

These ratings indicate how accurately the products classify legitimate applications and URLs, while also taking into account the interactions that each product has with the user. Ideally a product will either not classify a legitimate object or will classify it as safe. In neither case should it bother the user.

We also take into account the prevalence (popularity) of the applications and websites used in this part of the test, applying stricter penalties for when products misclassify very popular software and sites.

To understand how we calculate these ratings, see 6.3 Accuracy Ratings on page 16.

<table>

</tr>
</tbody>
</table>

Legitimate Software Ratings can indicate how well a vendor has tuned its detection engine.
6.1 Interaction Ratings

It’s crucial that anti-malware endpoint products not only stop – or at least detect – threats, but that they allow legitimate applications to install and run without misclassifying them as malware. Such an error is known as a ‘false positive’ (FP).

In reality, genuine FPs are quite rare in testing. In our experience it is unusual for a legitimate application to be classified as ‘malware’. More often it will be classified as ‘unknown’, ‘suspicious’ or ‘unwanted’ (or terms that mean much the same thing).

We use a subtle system of rating an endpoint’s approach to legitimate objects, which takes into account how it classifies the application and how it presents that information to the user. Sometimes the endpoint software will pass the buck and demand that the user decide if the application is safe or not. In such cases the product may make a recommendation to allow or block. In other cases, the product will make no recommendation, which is possibly even less helpful.

If a product allows an application to install and run with no user interaction, or with simply a brief notification that the application is likely to be safe, it has achieved an optimum result. Anything else is a Non-Optimal Classification/Action (NOCA).

We think that measuring NOCAs is more useful than counting the rarer FPs.

<table>

</tr>
<tr>
<td>Webroot SecureAnywhere Endpoint Protection</td>
</tr>
</tbody>
</table>

Products that do not bother users and classify most applications correctly earn more points than those that ask questions and condemn legitimate applications.
6.2 Prevalence Ratings

There is a significant difference between an endpoint product blocking a popular application such as the latest version of Microsoft Word and condemning a rare Iranian dating toolbar for Internet Explorer 6. One is very popular all over the world and its detection as malware (or something less serious but still suspicious) is a big deal. Conversely, the outdated toolbar won’t have had a comparably large user base even when it was new. Detecting this application as malware may be wrong, but it is less impactful in the overall scheme of things.

With this in mind, we collected applications of varying popularity and sorted them into five separate categories, as follows:

1. Very High Impact
2. High Impact
3. Medium Impact
4. Low Impact
5. Very Low Impact

Incorrectly handling any legitimate application will invoke penalties, but classifying Microsoft Word as malware and blocking it without any way for the user to override this will bring far greater penalties than doing the same for an ancient niche toolbar. In order to calculate these relative penalties, we assigned each impact category with a rating modifier, as shown in the table above.

<table>
<thead>
<tr>
<th>Impact Category</th>
<th>Rating Modifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>Very High Impact</td>
<td>5</td>
</tr>
<tr>
<td>High Impact</td>
<td>4</td>
</tr>
<tr>
<td>Medium Impact</td>
<td>3</td>
</tr>
<tr>
<td>Low Impact</td>
<td>2</td>
</tr>
<tr>
<td>Very Low Impact</td>
<td>1</td>
</tr>
</tbody>
</table>

Applications were downloaded and installed during the test, but third-party download sites were avoided and original developers’ URLs were used where possible. Download sites will sometimes bundle additional components into applications’ install files, which may correctly cause anti-malware products to flag adware. We remove adware from the test set because it is often unclear how desirable this type of code is.

The prevalence for each application and URL is estimated using metrics such as third-party download sites and the data from Alexa.com’s global traffic ranking system.

6.3 Accuracy Ratings

We calculate legitimate software accuracy ratings by multiplying together the interaction and prevalence ratings for each download and installation:

\[
\text{Accuracy rating} = \text{Interaction rating} \times \text{Prevalence rating}
\]

If a product allowed one legitimate, Medium impact application to install with zero interaction with the user, then its Accuracy rating would be calculated like this:

\[
\text{Accuracy rating} = 2 \times 3 = 6
\]

This same calculation is made for each legitimate application/site in the test and the results are summed and used to populate the graph and table shown under 6. Legitimate Software Ratings on page 14.
6.4 Distribution of Impact Categories

Endpoint products that were most accurate in handling legitimate objects achieved the highest ratings. If all objects were of the highest prevalence, the maximum possible rating would be 1,000 (100 incidents x (2 interaction rating x 5 prevalence rating)).

In this test there was a range of applications with different levels of prevalence. The table below shows the frequency:

<table>
<thead>
<tr>
<th>LEGITIMATE SOFTWARE CATEGORY FREQUENCY</th>

<td>13</td>
</tr>
<tr>
<td>Very Low Impact</td>
<td>4</td>
</tr>
</tbody>
</table>

7. Conclusions

Attacks in this test included threats that affect the wider public and more closely targeted individuals and organisations. You could say that we tested the products with ‘public’ malware and full-on hacking attacks. We introduced the threats in a realistic way such that threats seen in the wild on websites were downloaded from those same websites, while threats caught spreading through email were delivered to our target systems as emails.

All of the products tested are well-known and should do well in this test. While we do ‘create’ threats by using publicly available free hacking tools, we don’t write unique malware so there is no technical reason why any vendor being tested should do poorly.

Consequently, it’s not a shock to see all products handle the public threats very effectively. Even the weaker products protected the target systems in the vast majority of cases. Targeted attacks were handled perfectly by most.

Products from Kaspersky Lab, McAfee, Microsoft, Sophos, Symantec and Trend Micro protected against all of the public and targeted attacks. Trend Micro scored slightly lower because it neutralised some threats, while Sophos did not handle one legitimate application correctly. Most other products handled the legitimate applications correctly, with other exceptions being Microsoft and Webroot, which blocked one or two objects each.

Bitdefender’s product missed one targeted attack and two public ones, while FireEye’s product stopped all the targeted attacks and but missed four public threats. Webroot’s product stopped all but two of the public threats and, like FireEye, stopped all targeted attacks.

The leading products from Kaspersky Lab, McAfee, Microsoft, Sophos, Symantec, Trend Micro, Bitdefender and FireEye all win AAA awards.
APPENDIX A: Terms Used

<table>
<thead>
<tr>
<th>TERM</th>
<th>MEANING</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compromised</td>
<td>The attack succeeded, resulting in malware running unhindered on the target. In the case of a targeted attack, the attacker was able to take remote control of the system and carry out a variety of tasks without hindrance.</td>
</tr>
<tr>
<td>Blocked</td>
<td>The attack was prevented from making any changes to the target.</td>
</tr>
<tr>
<td>False positive</td>
<td>When a security product misclassifies a legitimate application or website as being malicious, it generates a ‘false positive’.</td>
</tr>
<tr>
<td>Neutralised</td>
<td>The exploit or malware payload ran on the target but was subsequently removed.</td>
</tr>
<tr>
<td>Complete Remediation</td>
<td>If a security product removes all significant traces of an attack, it has achieved complete remediation.</td>
</tr>
<tr>
<td>Target</td>
<td>The test system that is protected by a security product.</td>
</tr>
<tr>
<td>Threat</td>
<td>A program or sequence of interactions with the target that is designed to take some level of unauthorised control of that target.</td>
</tr>
<tr>
<td>Update</td>
<td>Security vendors provide information to their products in an effort to keep abreast of the latest threats. These updates may be downloaded in bulk as one or more files, or requested individually and live over the internet.</td>
</tr>
</tbody>
</table>

APPENDIX B: FAQs

A full methodology for this test is available from our website.
- The products chosen for this test were selected by SE Labs.
- The test was unsponsored.
- The test was conducted between 6th April to 11th June 2020.
- All products were configured according to each vendor’s recommendations, when such recommendations were provided.
- Malicious URLs and legitimate applications and URLs were independently located and verified by SE Labs.
- Targeted attacks were selected and verified by SE Labs.
- Malicious and legitimate data was provided to partner organisations once the test was complete.
- SE Labs conducted this endpoint security testing on physical PCs, not virtual machines.
- The web browser used in this test was Google Chrome. When testing Microsoft products Chrome was equipped with the Windows Defender Browser Protection browser extension (https://browserprotection.microsoft.com).

Q What is a partner organisation? Can I become one to gain access to the threat data used in your tests?

A Partner organisations benefit from our consultancy services after a test has been run. Partners may gain access to low-level data that can be useful in product improvement initiatives and have permission to use award logos, where appropriate, for marketing purposes. We do not share data on one partner with other partners. We do not partner with organisations that do not engage in our testing.

Q I am a security vendor and you tested my product without permission. May I access the threat data to verify that your results are accurate?

A We are willing to share a certain level of test data with non-partner participants for free. The intention is to provide sufficient data to demonstrate that the results are accurate. For more in-depth data suitable for product improvement purposes we recommend becoming a partner.
APPENDIX C: Product Versions

The table below shows the service's name as it was being marketed at the time of the test.

<table>
<thead>
<tr>
<th>Vendor</th>
<th>Product</th>
<th>Build Version (start)</th>
<th>Build Version (end)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Engine Version: 7.76257</td>
<td></td>
