INTELLIGENCE-LED TESTING

Endpoint Security

Home

Oct - Dec 2023

EPS
PROTECTION

SE Labs tested a variety of anti-malware (aka ‘anti-virus’; aka ‘endpoint security’) products from a range of well-known vendors in an effort to judge which were the most effective.

Each product was exposed to the same threats, which were a mixture of targeted attacks using well-established techniques and public email and web-based threats that were found to be live on the internet at the time of the test.

The results indicate how effectively the products were at detecting and/or protecting against those threats in real time.

Introduction

Critical Endpoint Protection Evaluations

Realistic attacks for useful results

Endpoint protection is a critical component of any organisation's cybersecurity strategy. And if it's critical then you should test it. And have others run assessments too.

Testing endpoint protection involves evaluating the effectiveness of the security solutions that are deployed on endpoint devices such as desktops, laptops and mobile devices. Endpoint protection testing is necessary because endpoints are often the target of cyberattacks and can be used as a gateway to gain access to sensitive data.

SE Labs has extensive experience in endpoint protection testing, and we have found that it is essential to conduct these tests regularly to ensure that the security vendors are keeping them up to date and effective. Our testing methodology involves replicating real-world cyberattack scenarios and evaluating how well the endpoint security solutions perform in detecting, preventing, and mitigating those attacks.

One of the key aspects of endpoint protection testing is the use of realistic attack scenarios. Our team of experts analyses the latest threat intelligence and creates attack

scenarios that closely mimic the tactics, techniques, and procedures used by real-world cybercriminals. By doing so, we can determine how well the endpoint security solutions perform in detecting and preventing these attacks.

At SE Labs, we are committed to helping organisations improve their cybersecurity posture by providing comprehensive and realistic endpoint protection testing services. This report is the first step when considering which products to use. For more in-depth testing, please [get in touch](#) for a more bespoke experience.

If you spot a detail in this report that you don't understand, or would like to discuss, please [contact us](#). SE Labs uses current threat intelligence to make our tests as realistic as possible. To learn more about how we test, how we define 'threat intelligence' and how we use it to improve our tests please visit our [website](#) and follow us on [LinkedIn](#).

Executive Summary

Product Names

It is good practice to stay up to date with the latest version of your chosen endpoint security product. We made best efforts to ensure that each product tested was the very latest version running with the most recent updates to give the best possible outcome.

For specific build numbers, see **Appendix C: Product Versions** on page 19.

Executive Summary			
Products Tested	Protection Accuracy Rating (%)	Legitimate Accuracy Rating (%)	Total Accuracy Rating (%)
Avast Free Antivirus	100%	100%	100%
Kaspersky Plus	100%	100%	100%
Microsoft Defender Antivirus (consumer)	100%	100%	100%
NortonLifeLock Norton360	100%	100%	100%
Sophos Home Premium	98%	100%	99%
Panda Free Antivirus	97%	100%	99%
McAfee Total Protection	96%	100%	99%
Webroot Antivirus	83%	100%	94%
Comodo Antivirus	78%	100%	92%

Products highlighted in green were the most accurate, scoring 85 per cent or more for Total Accuracy. Those in yellow scored less than 85 but 75 or more. Products shown in red scored less than 75 per cent.

For exact percentages, see **1. Total Accuracy Ratings** on page 6.

- **The endpoints were generally effective at handling general threats from cyber criminals ...**

All products were very capable of handling public email- and web-based threats such as those used by criminals to attack Windows PCs, tricking users into running malicious files or running scripts that download and run malicious files.

- **... but targeted attacks caused problems for some of the products.**

Five of the nine products provided complete protection against the targeted attacks used in this test. It only takes one targeted attack to breach an organisation, so this is concerning result.

- **False positives were not an issue for the products.**

Most of the products were perfectly good at correctly classifying legitimate applications and websites.

- **Which products were the most effective?**

Products from **Microsoft, Kaspersky, Norton and Avast** produced extremely good results due to a combination of their ability to block malicious URLs, handle exploits and correctly classify legitimate application and websites. All products performed well enough to achieve AAA awards.

1. Total Accuracy Ratings

Judging the effectiveness of an endpoint security product is a subtle art, and many factors are at play when assessing how well it performs. To make things easier we've combined all the different results from this report into one easy-to-understand graph.

The graph below takes into account not only each product's ability to detect and protect against threats, but also its handling of non-malicious objects such as web addresses (URLs) and applications.

Not all protections, or detections for that matter, are equal. A product might completely block a URL, which stops the threat before it can even start its intended series of malicious events. Alternatively, the product might allow a web-based exploit to execute but prevent it from downloading any further code to the target. In another case malware might run on the target for a short while before its behaviour is detected and its code is deleted or moved to a safe 'quarantine' area for future analysis. We take these outcomes into account when attributing points that form final ratings.

For example, a product that completely blocks a threat is rated more highly than one that allows a threat to run for a while before eventually evicting it. Products that allow all malware infections, or that block popular legitimate applications, are penalised heavily.

Categorising how a product handles legitimate objects is complex, and you can find out how we do it in **6. Legitimate Software Ratings** on page 14.

Total Accuracy Ratings			
Product	Total Accuracy Rating	Total Accuracy (%)	Award
Kaspersky Plus	1,136	100%	AAA
Microsoft Defender Antivirus (consumer)	1,136	100%	AAA
NortonLifeLock Norton360	1,136	100%	AAA
Avast Free Antivirus	1,135	100%	AAA
Sophos Home Premium	1,129	99%	AAA
Panda Free Antivirus	1,122	99%	AAA
McAfee Total Protection	1,119	99%	AAA
Webroot Antivirus	1,067	94%	AA
Comodo Antivirus	1,046	92%	AA

2. Threat Responses

Full Attack Chain: Testing every layer of detection and protection

Attackers start from a certain point and don't stop until they have either achieved their goal or have reached the end of their resources (which could be a deadline or the limit of their abilities).

This means, in a test, the tester needs to begin the attack from a realistic first position, such as sending a phishing email or setting up an infected

website, and moving through many of the likely steps leading to actually stealing data or causing some other form of damage to the network.

If the test starts too far into the attack chain, such as executing malware on an endpoint, then many products will be denied opportunities to use the full extent of their protection and detection abilities.

If the test concludes before any 'useful' damage or theft has been achieved, then similarly the product may be denied a chance to demonstrate its abilities in behavioural detection and so on.

Attack Stages

The illustration below shows some typical stages of an attack. In a test each of these should be

Attack Chain: How Hackers Progress

Figure 1. A typical attack starts with an initial contact and progresses through various stages, including reconnaissance, stealing data and causing damage.

Figure 2. This attack was initially successful but only able to progress as far as the reconnaissance phase.

Figure 3. A more successful attack manages to steal passwords but wholesale data theft and destruction was blocked.

attempted to determine the security solution’s effectiveness. This test’s results record detection and protection for each of these stages.

We measure how a product responds to the first stages of the attack with a detection and/ or protection rating. Sometimes products allow threats to run but detect them. Other times they might allow the threat to run briefly before neutralising it. Ideally they detect and block the threat before it has a chance to run. Products may delete threats or automatically contain them in a ‘quarantine’ or other safe holding mechanism for later analysis.

Should the initial attack phase succeed we then measure post-exploitation stages, which are represented by steps two through to seven

below. We broadly categorise these stages as: Access (step 2); Action (step 3); Escalation (step 4); and Post-escalation (step 5).

In figure 1. you can see a typical attack running from start to end, through various ‘hacking’ activities. This can be classified as a fully successful breach.

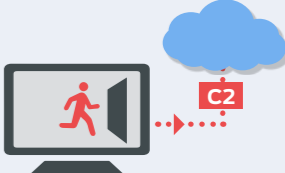

In figure 2. a product or service has interfered with the attack, allowing it to succeed only as far as stage 3, after which it was detected and neutralised. The attacker was unable to progress through stages 4 and onwards.

It is possible that attackers will not cause noticeable damage during an attack. It may be that their goal is persistent presence on the

systems to monitor for activities, slowly steal information and other more subtle missions.

In figure 3. the attacker has managed to progress as far as stage five. This means that the system has been seriously compromised. The attacker has a high level of access and has stolen passwords. However, attempts to exfiltrate data from the target were blocked, as were attempts to damage the system.

The table below shows how a typical way in which security testers illustrate attackers’ behaviour. It is largely the same as our images above, but more detailed.

MITRE Example Attack Chain Details							
Initial Access	Execution	Privilege Escalation	Credential Access	Discovery	Collection	Command and Control	Exfiltration
Spear Phishing via Service	Command-Line Interface	Bypass UAC	Input Capture	File and Directory Discovery	Input Capture	Data Encoding	Exfiltration Over C2 Channel
Spear Phishing Link	PowerShell		OS Credential Dumping	Process Discovery	Data from Local System	Data Obfuscation	
	Scripting		System Information Discovery				
							
Spear Phishing Link	Scripting	Bypass UAC	OS Credential Dumping	Process Discovery	Data from Local System	Data Obfuscation	Exfiltration Over C2 Channel

3. Protection Ratings

The results below indicate how effectively the products dealt with threats. Points are earned for detecting the threat and for either blocking or neutralising it.

■ Detected (+1)

If the product detects the threat with any degree of useful information, we award it one point.

■ Blocked (+2)

Threats that are disallowed from even starting their malicious activities are blocked. Blocking products score two points.

■ Complete Remediation (+1)

If, in addition to neutralising a threat, the product removes all significant traces of the attack, it gains an additional one point.

■ Neutralised (+1)

Products that kill all running malicious processes 'neutralise' the threat and win one point.

■ Persistent Neutralisation (-2)

This result occurs when a product continually blocks a persistent threat from achieving its aim, while not removing it from the system.

■ Compromised (-5)

If the threat compromises the system, the product loses five points. This loss may be reduced to four points if it manages to detect the threat (see Detected, above), as this at least

alerts the user, who may now take steps to secure the system.

Rating Calculations

We calculate the protection ratings using the following formula:

$$\begin{aligned} \text{Protection Rating} = & \\ & (1 \times \text{number of Detected}) + \\ & (2 \times \text{number of Blocked}) + \\ & (1 \times \text{number of Neutralised}) + \\ & (1 \times \text{number of Complete remediation}) + \\ & (-5 \times \text{number of Compromised}) \end{aligned}$$

The 'Complete remediation' number relates to cases of neutralisation in which all significant traces of the attack were removed from the target.

These ratings are based on our opinion of how important these different outcomes are. You may have a different view on how seriously you treat a 'Compromise' or 'Neutralisation without complete remediation'. If you want to create your own rating system, you can use the raw data from **5. Protection Details** on page 13 to roll your own set of personalised ratings.

Targeted Attack Scoring

The following scores apply only to targeted attacks and are cumulative, ranging from -1 to -5.

■ Access (-1)

If any command that yields information about the

target system is successful this score is applied. Examples of successful commands include listing current running processes, exploring the file system and so on. If the first command is attempted and the session is terminated by the product without the command being successful the score of Neutralised (see above) will be applied.

■ Action (-1)

If the attacker is able to exfiltrate a document from the target's Desktop of the currently logged in user then an 'action' has been successfully taken.

■ Escalation (-2)

The attacker attempts to escalate privileges to NT Authority/System. If successful, an additional two points are deducted.

■ Post-Escalation Action (-1)

After escalation the attacker attempts actions that rely on escalated privileges. These include attempting to steal credentials, modifying the file system and recording keystrokes. If any of these actions are successful then a further penalty of one point deduction is applied.

Enterprise Security Testing Services for CISOs

Elevate your cyber security strategy with SE Labs, the world's leading security testing organisation.

SE Labs works with large organisations to support CISOs and their security teams:

- Validate existing combination of security products and services.
- Provide expert partnership when choosing and deploying new security technologies.

SE Labs provides in-depth evaluations of the cyber security that you are considering, tailored to the exact, unique requirements of your business.

For an honest, objective and well-informed view of the cyber security industry contact us now at

selabs.uk/contact

Protection Accuracy		
Product	Protection Accuracy	Protection Accuracy (%)
Kaspersky Plus	400	100%
Microsoft Defender Antivirus (consumer)	400	100%
NortonLifeLock Norton360	400	100%
Avast Free Antivirus	399	100%
Sophos Home Premium	393	98%
Panda Free Antivirus	386	97%
McAfee Total Protection	383	96%
Webroot Antivirus	331	83%
Comodo Antivirus	310	78%

Average 95%

Protection Ratings are weighted to show that how products handle threats can be subtler than just 'win' or 'lose'.

4. Protection Scores

This graph shows the overall level of protection, making no distinction between neutralised and blocked incidents.

For each product we add Blocked and Neutralised cases together to make one simple tally.

Protection Scores	
Product	Protection Score
Avast Free Antivirus	100
Kaspersky Plus	100
Microsoft Defender Antivirus (consumer)	100
NortonLifeLock Norton360	100
Sophos Home Premium	100
McAfee Total Protection	98
Panda Free Antivirus	98
Comodo Antivirus	94
Webroot Antivirus	90

Protection Scores are a simple count of how many times a product protected the system.

5. Protection Details

These results break down how each product handled threats into some detail. You can see how many detected a threat and the levels of protection provided.

Products sometimes detect more threats than they protect against. This can happen when they recognise an element of the threat but aren't equipped to stop it. Products can also provide protection even if they don't detect certain threats. Some threats abort on detecting specific endpoint protection software.

Protection Details					
Product	Detected	Blocked	Neutralised	Compromised	Protected
Avast Free Antivirus	100	100	0	0	100
Kaspersky Plus	100	100	0	0	100
Microsoft Defender Antivirus (consumer)	100	100	0	0	100
NortonLifeLock Norton360	100	100	0	0	100
Sophos Home Premium	100	99	1	0	100
McAfee Total Protection	98	98	0	2	98
Panda Free Antivirus	98	98	0	2	98
Comodo Antivirus	100	94	0	6	94
Webroot Antivirus	98	89	1	10	90

6. Legitimate Software Ratings

These ratings indicate how accurately the products classify legitimate applications and URLs, while also taking into account the interactions that each product has with the user. Ideally a product will either not classify a legitimate object or will classify it as safe. In neither case should it bother the user.

We also take into account the prevalence (popularity) of the applications and websites used in this part of the test, applying stricter penalties for when products misclassify very popular software and sites.

To understand how we calculate these ratings, see **6.3 Accuracy Ratings** on page 16.

Legitimate Software Ratings		
Product	Legitimate Accuracy Rating	Legitimate Accuracy (%)
Avast Free Antivirus	736	100%
Comodo Antivirus	736	100%
Kaspersky Plus	736	100%
McAfee Total Protection	736	100%
Microsoft Defender Antivirus (consumer)	736	100%
NortonLifeLock Norton360	736	100%
Panda Free Antivirus	736	100%
Sophos Home Premium	736	100%
Webroot Antivirus	736	100%

Legitimate Software Ratings can indicate how well a vendor has tuned its detection engine.

6.1 Interaction Ratings

It's crucial that anti-malware endpoint products not only stop – or at least detect – threats, but that they allow legitimate applications to install and run without misclassifying them as malware. Such an error is known as a 'false positive' (FP).

In reality, genuine FPs are quite rare in testing. In our experience it is unusual for a legitimate application to be classified as 'malware'. More often it will be classified as 'unknown', 'suspicious' or 'unwanted' (or terms that mean much the same thing).

We use a subtle system of rating an endpoint's approach to legitimate objects, which takes into account how it classifies the application and how it presents that information to the user. Sometimes the endpoint software will pass the buck and demand that the user decide if the application is safe or not. In such cases the product may make a recommendation to allow or block. In other cases, the product will make no recommendation, which is possibly even less helpful.

If a product allows an application to install and run with no user interaction, or with simply a brief notification that the application is likely to be safe, it has achieved an optimum result. Anything else is a Non-Optimal Classification/Action (NOCA). We think that measuring NOCAs is more useful than counting the rarer FPs.

	None (allowed)	Click to Allow (default allow)	Click to Allow/Block (no recommendation)	Click to Block (default block)	None (blocked)	
Object is Safe	2	1.5	1			A
Object is Unknown	2	1	0.5	0	-0.5	B
Object is not Classified	2	0.5	0	-0.5	-1	C
Object is Suspicious	0.5	0	-0.5	-1	-1.5	D
Object is Unwanted	0	-0.5	-1	-1.5	-2	E
Object is Malicious				-2	-2	F
	1	2	3	4	5	

Interaction Ratings	
Product	None (allowed)
Avast Free Antivirus	100
Comodo Antivirus	100
Kaspersky Plus	100
McAfee Total Protection	100
Microsoft Defender Antivirus (consumer)	100
NortonLifeLock Norton360	100
Panda Free Antivirus	100
Sophos Home Premium	100
Webroot Antivirus	100

Products that do not bother users and classify most applications correctly earn more points than those that ask questions and condemn legitimate applications.

6.2 Prevalence Ratings

There is a significant difference between an endpoint product blocking a popular application such as the latest version of Microsoft Word and condemning a rare Iranian dating toolbar for Internet Explorer 6. One is very popular all over the world and its detection as malware (or something less serious but still suspicious) is a big deal. Conversely, the outdated toolbar won't have had a comparably large user base even when it was new. Detecting this application as malware may be wrong, but it is less impactful in the overall scheme of things.

With this in mind, we collected applications of varying popularity and sorted them into five separate categories, as follows:

1. **Very High Impact**
2. **High Impact**
3. **Medium Impact**
4. **Low Impact**
5. **Very Low Impact**

Incorrectly handling any legitimate application will invoke penalties, but classifying Microsoft Word as malware and blocking it without any way for the user to override this will bring far greater penalties than doing the same for an ancient niche toolbar. In order to calculate these relative penalties, we assigned each impact category with a rating modifier, as shown in the table above.

Legitimate Software Prevalence Rating Modifiers	
Impact Category	Rating Modifier
Very High Impact	5
High Impact	4
Medium Impact	3
Low Impact	2
Very Low Impact	1

Applications were downloaded and installed during the test, but third-party download sites were avoided and original developers' URLs were used where possible. Download sites will sometimes bundle additional components into applications' install files, which may correctly cause anti-malware products to flag adware. We remove adware from the test set because it is often unclear how desirable this type of code is.

The prevalence for each application and URL is estimated using metrics such as third-party download sites and the data from Tranco.com's global traffic ranking system.

6.3 Accuracy Ratings

We calculate legitimate software accuracy ratings by multiplying together the interaction and prevalence ratings for each download and installation:

Accuracy rating = Interaction rating x Prevalence rating

If a product allowed one legitimate, Medium impact application to install with zero interaction with the user, then its Accuracy rating would be calculated like this:

Accuracy rating = 2 x 3 = 6

This same calculation is made for each legitimate application/site in the test and the results are summed and used to populate the graph and table shown under **6. Legitimate Software Ratings** on page 14.

6.4 Distribution of Impact Categories

Endpoint products that were most accurate in handling legitimate objects achieved the highest ratings. If all objects were of the highest prevalence, the maximum possible rating would be 1,000 (100 incidents x (2 interaction rating x 5 prevalence rating)).

In this test there was a range of applications with different levels of prevalence. The table below shows the frequency:

Legitimate Software Category Frequency	
Prevalence Rating	Frequency
Very High Impact	32
High Impact	32
Medium Impact	16
Low Impact	12
Very Low Impact	8

7. Conclusions

Attacks in this test included threats that affect the wider public and more closely targeted individuals and organisations. You could say that we tested the products with 'public' malware and full-on hacking attacks.

We introduced the threats in a realistic way such that threats seen in the wild on websites were downloaded from those same websites, while threat caught spreading through email were delivered to our target systems as emails.

All of the products tested are well-known and should do well in this test. While we do 'create' threats by using publicly available free hacking tools, we do not write unique malware so there is no technical reason why any vendor being tested should do poorly.

The results were generally strong, particularly in the way that the products handled public threats. These are threats that are live on the Internet on the day that the products are tested. Excellent results from all the products indicate both familiarity with common threats and frequent updates to keep databases current.

Four of the nine products stopped all of the attacks, including those that are targeted. Targeted attacks are usually more of a challenge because they are not widely known. The products that achieved 100% Protection Accuracy Ratings belonged to **Norton**, **Microsoft**, **Kaspersky** and **Avast**. The products from **Sophos**, **Panda** and **McAfee** came in strongly behind, each missing only one or two targeted attacks.

Indeed, **Sophos Home Premium** was able to neutralise the single threat that it did not block outright.

Panda Free Antivirus and **McAfee Total Protection** only missed two targeted attacks each. **Comodo Antivirus** detected all of the targeted threats but did not block six of them. **Webroot Antivirus** neutralised one threat but was compromised by ten.

All the products handled legitimate applications and websites correctly, with no mistakes. The installation and execution of legitimate applications were allowed, with no ambiguous warnings.

Almost all the products in this test win AAA awards. The strongest, from **Norton**, **Microsoft**, **Kaspersky** and **Avast** stopped all threats and allowed all legitimate applications. Also outstanding were **Sophos**, **Panda** and **McAfee** which were only a single percentage point shy of a perfect total accuracy score. **Webroot** and **Comodo** received total ratings of 94% and 92% respectively, making them AA awardees.

Appendices

Appendix A: Terms Used

Term	Meaning
Compromised	The attack succeeded, resulting in malware running unhindered on the target. In the case of a targeted attack, the attacker was able to take remote control of the system and carry out a variety of tasks without hindrance.
Blocked	The attack was prevented from making any changes to the target.
False positive	When a security product misclassifies a legitimate application or website as being malicious, it generates a 'false positive'.
Neutralised	The exploit or malware payload ran on the target but was subsequently removed.
Complete Remediation	If a security product removes all significant traces of an attack, it has achieved complete remediation.
Target	The test system that is protected by a security product.
Threat	A program or sequence of interactions with the target that is designed to take some level of unauthorised control of that target.
Update	Security vendors provide information to their products in an effort to keep abreast of the latest threats. These updates may be downloaded in bulk as one or more files, or requested individually and live over the internet.

Appendix B: FAQs

A **full methodology** for this test is available from our website.

- The products chosen for this test were selected by SE Labs.
- The test was unsponsored.
- The test was conducted between 19th September and 21st November 2023.
- All products were configured according to each vendor's recommendations, when such recommendations were provided.
- Malicious URLs and legitimate applications and URLs were independently located and verified by SE Labs.
- Targeted attacks were selected and verified by SE Labs.
- Malicious and legitimate data was provided to partner organisations once the test was complete.
- The web browser used in this test was Google Chrome. When testing Microsoft products Chrome was equipped with the Windows Defender Browser Protection browser extension (<https://browserprotection.microsoft.com>). We allow other browser extensions when a tested product requests a user install one or more.

Q What is a partner organisation? Can I become one to gain access to the threat data used in your tests?

A Partner organisations benefit from our consultancy services after a test has been run. Partners may gain access to low-level data that can be useful in product improvement initiatives and have permission to use award logos, where appropriate, for marketing purposes. We do not share data on one partner with other partners. We do not partner with organisations that do not engage in our testing.

Q I am a security vendor and you tested my product without permission. May I access the threat data to verify that your results are accurate?

A We are willing to share a certain level of test data with non-partner participants for free. The intention is to provide sufficient data to demonstrate that the results are accurate. For more in-depth data suitable for product improvement purposes we recommend becoming a partner.

Appendix C: Product Versions

The table below shows the service's name as it was being marketed at the time of the test.

Product Versions			
Vendor	Product	Build Version (start)	Build Version (end)
Avast	Free Antivirus	Program Version: 23.8.6078 (build 23.8.8416.762) Virus Definitions Version: 230831-0 UI Version: 1.0.774	Program Version: 23.8.6078 (build 23.8.8416.794) Virus Definitions Version: 231123-12 UI Version: 1.0.788
Comodo	Antivirus	Product Version: 12.2.2.8012	Product Version: 12.2.2.8012
Kaspersky	Plus	21.14.5.462	21.15.8.493
McAfee	Total Protection	McAfee Total Protection Version: 1.10.231 Antivirus Version: 1519.0 Secure VPN Version: 1.10 Tracker Remover Version: 1.10 Shredder Version: 1.10 Advanced Firewall Version: 1.10	McAfee Total Protection Version: 1.11.279 Antivirus Version: 1604.0 Secure VPN Version: 1.11 Tracker Remover Version: 1.11 Shredder Version: 1.11 Advanced Firewall Version: 1.11
Microsoft	Defender Antivirus (consumer)	Antimalware Client Version: 4.18.23080.2006 Engine Version: 1.1.23080.2005 Antivirus Version: 1.397.89.0 Anti-spyware Version: 1.397.89.0	Antimalware Client Version: 4.18.23100.2009 Engine Version: 1.1.23100.2009 Antivirus Version: 1.401.1093.0 Anti-spyware Version: 1.401.1093.0
NortonLifeLock	Norton360	22.23.6.5	22.23.10.10
Panda	Free Antivirus	22.00.01	22.00.01
Sophos	Home Premium	4.3.1.2	4.3.1.2
Webroot	Antivirus	9.0.34.54	9.0.34.54

Appendix D: Attack Types

The table below shows how each product protected against the different types of attacks used in the test.

Attack Types			
Product	General Attack	Targeted Attack	Protected (%)
Avast Free Antivirus	75	25	100%
Kaspersky Plus	75	25	100%
Microsoft Defender Antivirus (consumer)	75	25	100%
NortonLifeLock Norton360	75	25	100%
Sophos Home Premium	75	25	100%
